GOLDENVEYSE, A. L.

Goldenveiser, A. L. Procedures of integration of equations of the theory of thin shells. Appl. Math. Mech. [Akad. Nauk SSSR, Izv. Mat. Mech.] 10, 387-396 (1946). (Russian. English summary)

The author gives a method of determining the edge effect along those contours of the shell whose tangents do not coincide with the asymptotic lines of the middle surface. The integration of the system of equations of the shell theory is reduced, in several cases, to the integration of momentless theory. This paper is a sequel to the author's earlier paper [same journal 9, 465-478 (1945); these Rev. 7, 351].

Goldenweiser, A. L. Momentless theory of shells whose middle surface is of a curve of the second order. Appl. Math. Mech. [Akad. Nauk SSSR, Prikl. Mat. Mech.] 11, 285-290 (1947). (Russian. English summary)

[A more accurate translation of the Russian title would omit the phrase "of a curve."] This note indicates that the solution of the problem of momentless shell theory for shells whose middle surfaces are quadrics is reducible, by a suitable change of dependent and independent variables, to the integration of Poisson's or wave equations.

GOLDENWEISER, A. L.

Goldenweiser, A. L. Approximate calculation of thin shells of zero Gauss curvature. Akad. Nauk SSSR, Prikl. Mat. Mekh. 11, 409-422 (1947). (Russian. English summary)

The main object of this paper is a qualitative analysis of stressed states in thin elastic shells with developable saddle surfaces. The paper also contains an outline of the methods of approximate calculation of stresses. The shell is covered by a net of lines of curvature α, β (the α -lines are of zero curvature) so that the first fundamental form for the surface is of the type $ds^2 = d\alpha^2 + B^2 d\beta^2$. In this case Love's general equations of the shell theory are reducible to two differential equations for the stress functions l and m from which the forces, moments, and deformations can be computed by differentiation. These equations are:

$$\frac{\lambda^2}{B^2} \frac{\partial}{\partial \alpha} \frac{\partial l}{\partial \alpha} - \frac{\lambda^2 h^2}{3(1-\sigma^2)} N(m, \sigma) = 0,$$

$$\frac{\lambda^2}{B^2} \frac{\partial}{\partial \alpha} \frac{\partial m}{\partial \alpha} + \lambda^2 N(l, -\sigma) = 0,$$

where λ^2 and $\lambda^2 h^2$ are introduced to make the terms of these equations have the dimensions of l ; for cylindrical shells ($\partial B / \partial \alpha = 0$),

$$N(F) = \frac{1}{B} \frac{\partial}{\partial \beta} \frac{\partial B}{\partial \beta} \frac{\partial}{\partial \beta} \frac{1}{B} \frac{\partial}{\partial \beta} \frac{\partial F}{\partial \beta} + \frac{1}{BR} \frac{\partial}{\partial \beta} \frac{1}{B} \frac{\partial F}{\partial \beta}$$

R being the radius of curvature of the β -line; for noncylindrical shells ($\partial B / \partial \alpha \neq 0$) $N(F)$, in addition to the terms

given above, contains the term

$$-\frac{1}{B} \frac{\partial}{\partial \beta} \frac{1}{B} \frac{\partial}{\partial \alpha} \left(\frac{\partial}{\partial \alpha} \frac{1}{B} \frac{\partial B}{\partial \alpha} \right) \frac{\partial F}{\partial \beta}$$

For conical and cylindrical shells the system can be integrated approximately in the form of a series involving trigonometric and Bessel functions provided certain restrictions on the lengths of the shells and on the generatrix angle are imposed.

Several results obtained in the author's two earlier papers [same journal 9, 463-478 (1945); 10, 387-396 (1946); these Rev. 7, 351; 8, 241], dealing with thin shells of zero Gaussian curvature which are so stressed that the state of stress can be decomposed into a momentless state and into a state produced by moments and boundary effects, appear as special cases in this more general treatment.

GOLDENVEYZER, A. L.

Gol'denveizer, A. L., and Laz'e, A. I. On the mathematical theory of the equilibrium of elastic shells. (Survey of the work published in the USSR.) Akad. Nauk SSSR. Prikl. Mat. Meh. 11, 565-592 (1947). (Russian)

This is a condensed survey of the research literature on the subject published in Russia during the past decade. Three distinct directions are discernible: (a) theoretical investigations based on the fundamental equations of the mathematical theory of elasticity; (b) work on stability and vibrations; (c) papers concerned with the engineering applications of the theory. This survey is concerned only with the first aspect. The development surveyed in this article falls into three categories: (a) formulation of the basic equations of the theory of thin shells, which extends the classical theory of Love with the aid of modern tools of differential geometry; (b) specialization of the general three-dimensional problem of the theory of elasticity to a two-dimensional one by introducing certain geometrical hypotheses and physical assumptions; papers in this category are concerned with the analysis of the nature of the simplifications and with the study of the magnitude of errors inherent in them; (c) integration of the equations formulated in category (a). This is accomplished by replacing the complete system of equations by special systems yielding the information about the "edge effect" and the behavior in the vicinity of concentrated loads.

In addition to the account of the general investigations falling in these categories, the survey contains a résumé of several problems of integration of systems of equations associated with specific geometrical forms. These include spherical shells, conical shells and shells with variable Gaussian curvature. The survey concludes with a bibliography of 45 items. J. S. Sobotnikoff (Los Angeles, Calif.)

This work differs from others on thin-walled rods in that it does not make use of special hypotheses based on qualitative analysis of integrals of equations as found in the theory of shells. Purpose of its investigation is to determine approximately the basic stressed state in a rod span loaded by transverse load R and system of forces and moments T applied to terminal transverse section. It is

Text Data

Coverage: The theory of shells as based on the assumption of the inalterability of the normal element is considered in this book. It is further assumed that the materials are isotropic and obey Hook's law generalized, and that the second powers of deformations, displacements, and angles of return are sufficiently small to be neglected. The author made an effort to present as completely as possible the many existing approximate methods of calculation of shells. The book is the result of many years of the author's research. It is divided into five parts, each part being a complete entity which may be studied separately.

Cements, Limes, and Plastics

Autoclave method of making asbestos-cement shingles. T. M. BERKOVICH, I. L. RABINOV, AND V. L. GOL'DENVEISER. *Tsement*, 19 [4] 19-23 (1953).—In the existing method of making asbestos-cement shingles, high-grade Portland cement is used as the bond. The shingles are steamed at 60° to 60°C. for 8 to 16 hr. and then hardened in storage for 7 to 10 days. An improvement of this method involves the addition of not less than 50% finely ground quartz sand to the cement and steaming in an autoclave at 8 atm. pressure for 8 hr.

GOLDENVEYZER, A. L.

Gol'denveizer, A. L. On the calculation of shells with concentrated forces. Akad. Nauk SSSR. Prikl. Mat. Meh. 18, 181-186 (1954). (Russian)

There are two methods of calculating shells on concentrated forces. The first one starts with a distributed load acting in a small region which is allowed to shrink to a point, the load accordingly increasing infinitely at the same time. The second method consists of constructing a function satisfying the elasticity differential equations which has a certain defined singularity in the neighborhood of the point of application of the concentrated force. The author considers the second method only, which is mathematically very convenient, but which can be used only if the nature of the singularity is known beforehand. The author uses the following singularity: $r^2 \ln r$.

 AUTHOR GOL'DENVEYZER A.L.
 TITLE An improvement of the theory of the simple edge effect.
 PERIODICAL Priklad.Mat.Mech. 20, 335-348 (1956)
 reviewed 1/1957

Edge effects which arise in the near of a contour which nowhere touches the asymptotic lines of the medium surface of a shell, have been treated until now in first approximation only. In the case of axial symmetric shells only Lurje has proposed a method the exactness of which corresponds to that one of the theory of shells. In the general case the complex unknown function

$$W = \sqrt{\frac{h^2}{3(1-\sigma^2)}} 2 E h w + i c$$

(h - half thickness of the shell, σ - coefficient of Poisson, E - Young modulus, w - normal flexure of the shell, c - tension function) is obtained from the differential equation

$$L(W) + \frac{h}{\lambda} \frac{1}{\sqrt{3(1-\sigma^2)}} N(W) = 0 \quad \lambda - \text{characteristic radius of curvature of the shell}$$

AUTHOR: Gol'denveyzer, A.L. (Moscow) SOV/24-58-4-19/39

TITLE: On Reissner's Theory of the Bending of Plates (O teorii izgiba plastinok Rayssnera)

PERIODICAL: Izvestiya Akademii Nauk SSSR, Otdeleniye Tekhnicheskikh Nauk, 1958, Nr 4, pp 102 - 109 (USSR)

ABSTRACT: The author discusses Reissner's paper (Ref 1) in which a thin plate of constant thickness is subjected to normal forces of variable intensity at the upper and lower boundaries of the plate. Body forces are assumed to be absent. Reissner's theory is described and its generalisation discussed. The following question is proposed: which has greater influence on the corrections introduced by the theory - the elastic phenomena at the boundary of the plate or those far from it? As an example an unloaded circular plate is considered at whose boundary are applied a bending moment, a transverse force and a twisting moment. It is shown that Reissner's theory gives corrections to the constants A_1 and A_2 corresponding to the classical theory and a new constant A_3 is defined. The stressed state (called by Reissner the boundary effect) associated

Card1/2

SCN/24-72-4-19/39

On Reissner's Theory of the Bending of Plates

with this constant has a strongly local character. In a special case of the above example, the author finds that Reissner's theory can give wrong corrections to the classical theory. This is because the theory is based on a hypothesis concerning phenomena far from the boundary of the plate, while phenomena near the boundary play an important part. In conclusion, Vlasov's theory (Ref 4) is discussed. It gives the same law for the distribution of the bending stresses. The two theories are compared inconclusively. There are 4 references, 2 of which are Soviet and 2 English.

"The geometrical criterion of the momentlessness of the state of stress of a thin elastic shell."

Report presented at the 10th International Congress of Applied Mechanics, (ICSU) Stresa, Italy, 31 August - 7 Sep 1960.

In the author's absence the paper was presented by Oniashvili. Momentlessness means that nearly everywhere in the shell (except in zones of edge effects), the bending stresses are not significant. Quantitatively, this can be defined by the relative magnitude of the membrane strain energy W_m and the bending strain energy W_b . Let the characteristic of the middle surface K be defined by the equation,

TEXT: The author generalizes results which he obtained for the
solution of some problems of the theory of thin elastic shells. The
equation

$$\Delta u(\epsilon) + L(u) = 0 \quad (1)$$

is considered, where $\epsilon > 0$ is a small parameter, L and N linear diffe-
rential operators with the orders l and n , $l < n$, and two independent
variables x and y . It is assumed that the coefficients of L and N are
sufficiently smooth and that x and y form a coordinate system similar
to the polar system, i. e. the curve $x = \epsilon y$ represents the boundary of
the finite simply connected domain.

PURPOSE: This book is intended for scientific and engineering personnel who are interested in recent work in theoretical and applied mechanics.

COVERAGE: The articles included in these transactions are arranged by general subject matter under the following heads: general and applied mechanics (5 papers), fluid mechanics (10 papers), and the mechanics of rigid bodies (8 papers). Besides the organizational personnel of the congress, no personalities are mentioned. Six of the papers in the present collection have no references; the remaining 17 contain approximately 1400 references in Russian, Ukrainian, English, German, Czechoslovak, Rumanian, French, Italian, and Dutch.

TITLE: Asymptotic properties of eigenvalues in the elastic-shell theory

PERIODICAL: Prikladnaya i teoreticheskaya fizika, v. 27, no. 4, 1964, 729-734

TEXT: Linear problems are considered of free oscillations and the stability of thin elastic shells; special attention being given to asymptotic properties of eigenvalues as a function of the density and configuration of the normal lines of the vibrations. It was shown by the author (R 1-17, A.L. Gol'denveyzer, Teoriya uprugikh tonkikh obolochek (Theory of thin elastic shells), GITIL, 1953) that in many cases, the approximate description of the stress-strain state of elastic shells reduces to the integration of equations:

$$L(G) = a^2 R^2 \Delta (2\Delta G) + W = 0 \quad a^2 = \frac{h^2}{12\rho^2(1-\nu^2)} \quad (1.1)$$

$$L(\Delta G) = \Delta(G) = 0$$

where G is the deflection of the normal of section, $R = a$

asymptotic properties

$$\frac{h}{2Eh} \phi^2 = k^{2\alpha-4} \frac{1}{v} \left(1 + R^2 + \frac{R^2}{5(1-\frac{1}{2})} n \right) \quad (2.1)$$

k is a parameter $\left(\frac{h}{R} \right)^{1/2} \quad (2.2)$

1, n and v are given by

$$\begin{aligned} k^2 \rho_1 &= \int_0^1 h(\alpha) d\alpha \int_0^1 n(\alpha) d\alpha \int_0^1 \phi^2 d\phi \\ k^2 \rho_2 &= \int_0^1 h(\alpha) d\alpha \int_0^1 n(\alpha) d\alpha \int_0^1 \phi^2 d\phi \\ k^2 \rho_3 &= \int_0^1 h(\alpha) d\alpha \int_0^1 n(\alpha) d\alpha \int_0^1 \phi^2 d\phi \end{aligned} \quad (2.3)$$

(p has yet to be determined); for q_0 one obtains:

$$q_0 = k^{2\alpha-4} \frac{1}{v} \left(1 + R^2 + \frac{R^2}{5(1-\frac{1}{2})} n \right) \quad (2.4)$$

where $L^{1+\alpha} v = \int_0^1 h(\alpha) d\alpha \int_0^1 n(\alpha) d\alpha \int_0^1 \phi^2 d\phi \quad (2.5)$

(x has yet to be determined), conditions in E_1 (2.1) are given by

asymptotic properties...

$$c = c_* \left[\frac{1}{2} (\cos k (l_1 + l_2) + \cos k (l_1 + l_2)) \right] \quad (3.1)$$

$$w = w_* \left[\cos k (l_1 + l_2) + \cos k (l_1 + l_2) \right]$$

where c_* , w_* , f_1 , f_2 , r_1 , r_2 are functions of α and ρ which can be chosen. It is required that w_* and c_* be non-negative. The stress-strain state D is considered, determined by (3.1) and (3.1). The density of the nodal lines of D increases with k , i.e. with (for given h/R); the number k is termed the index variability. By appropriately choosing f_1 and f_2 it is possible that state D should have two (or one) system of nodal lines which belong to two (or one) pre-assigned families of curves; by the appropriate choice of α it is possible (with fixed f_1 and f_2) to increase or to reduce the density of nodal lines. It is postulated that the functions f_1 , f_2 , w_* , c_* , r_1 , r_2 can be chosen in such a way that their variability should not be very large and that c and w should be sufficiently close to a solution of Eq. (1.1) - (2.1); with such a choice of these functions, formulas (3.1) and (3.6) give sufficiently exact values of ω^2 and c_0 . This postulate is verified for all cases, except when the middle

Card 4/7

S/000 / 1/000 / 000 / 012/021
D. 000 0000

Asymptotic problem

surface of the shell has negative curvature. Now the problem consists in constructing asymptotic (in ϵ) expressions for the integrals (6.5), (6.6) on the assumption that ϵ and η have the form (6.1). The condition of asymptotic stability is

$$\iint_{\Omega} [L_0 \epsilon^2 + L_1 \epsilon^3 + L_2 \epsilon^4] d\Omega \geq 0 \quad (10.3)$$

where L_0 is

$$L_0 = \frac{1}{2} \frac{1}{R^2} \frac{(\partial \eta)^2}{\partial \alpha^2} + \frac{1}{2} \frac{1}{R^2} \frac{(\partial \eta)^2}{\partial \beta^2}$$

this condition may be applied at all points of the region under investigation $L_0^* + L_0^* = 0$ (10.4)

It follows from (6.5) the quantities L_1 and L_2 will remain finite when $\epsilon \rightarrow 0$, if η is asymptotically close to η_0 if condition (10.3) is satisfied, and $\eta_0 = 0$ if (10.4) holds. If both relations do not hold on the shell, it is assumed that $\eta = 1$. For a shell of positive curvature (10.4) always holds. For zero curvature, (10.3) is satisfied if η is a stable equilibrium strain state. D has only one stable equilibrium state (asymptotic lines of

asymptotic properties

the middle of the γ curve, character is considered further, the asymptotic behavior of γ is considered in the case of a shell theory (on the basis of the asymptotic behavior of γ is positive, hence it is found that the asymptotic behavior of γ is characterized by the value γ_0).

(12.2)

γ_0 depends on γ and can assume only one of the three values: 2, 1, 0; (hence γ_0 can have only three values too). A typical (for shell theory) behavior of the eigenvalue γ increase with increasing number of nodal lines n ; this takes place only up to a certain point - then γ decreases to a characteristic value γ_0 ; thereupon the regular relationship is reestablished: increasing eigenvalues with an increasing number of nodal lines. In stability problems, the least value of the critical load is important. It is found, for which configuration of nodal lines, loss of stability occurs. For zero curvature, 2 cases may arise: in the first case, stability may be lost for one family of nodal lines which coincide with rectilinear patterns; in the second case stability is not

AUTHOR: Gol'denveyzer, A.L. (Moscow)

TITLE: Construction of an approximate theory of bending of plates by the method of asymptotic integration of the equations of elasticity theory

PERIODICAL: Prikladnaya matematika i mekhanika, v. 26, no. 4, 1962, 668 - 686

TEXT: The possibility of rendering more exact the classical theory of bending of plates is considered. The bending problem is formulated as a three-dimensional problem of elasticity theory which is solved by the iteration method; thereby it is assumed that one of the dimensions is small as compared to the other two. The stressed state of the plate is sought in the form of a sum of a slowly-decreasing (with distance from the plate edge) stressed state which is constructed by means of the principal iteration process, and of fast-decreasing stressed states, constructed by means of auxiliary iteration processes. Such an approach is often used in the asymptotic integration of differential equations and corresponds to the

Card 1/4

VB

S/040/62/026/004/004/013
D406/D301

Construction of an approximate ...

tions. The auxiliary iteration process is constructed in two different ways. In the first, the construction of the solution amounts to the integration of an harmonic equation, whereas in the second, the solution involves the integration of a biharmonic equation. Five types of boundary conditions are considered, and the corresponding equations are set up. These equations are used to determine the sought-for functions (the biharmonic function $\Phi(x, y)$, the harmonic function $\psi(x, y)$, and the biharmonic function $\Phi(x, y)$). The function $\psi(x, y)$ can be expressed in terms of $\Phi(x, y)$. The main consequence of the above results is as follows: the stressed state has 3 components (the principal stressed state, the stressed state of edge twisting, and the stressed state of plane edge deformation). The principal stressed state corresponds to the principal iteration process, whereas the other stressed states correspond to the auxiliary processes. With such an approach, classical theory can be considered as an approximate method, based on the principal iteration process only, for which only the first approximation is constructed. The fundamental difference between the proposed method and classical theory, consists in introducing the auxiliary iteration processes, i.e. the processes constructed by integration of differential equations.

TITLE: Development of an approximate shell theory by the asymptotic integration of the elasticity-theory equations

SOURCE: Prikladnaya matematika i mekhanika, v. 27, no. 4, 1963, 593-608

TOPIC TAGS: approximate shell theory, asymptotic integration, shell theory

ABSTRACT: An asymptotic method of integration of differential equations of the elasticity theory is proposed, by means of which an approximate theory of shells can be established with a desired degree of accuracy in a way analogous to that used earlier by the author to develop an approximate theory of flexure of plates (Postroyeniye priblizhennoy teorii izgiba plastinki metodom asimptoticheskogo integrirovaniya uravneniy teorii uprugosti, PNM, 1962, v. 26, no. 4). This is closely associated with the method of asymptotic integration of differential equations of the theory of shells discussed in the author's monograph Teoriya uprugikh tonkikh obolochek, Gostekhizdat, 1953. Tensor analysis is applied in the representation and solution of the initial system of differential equations

Card 1/2

L 12946-63

ACCESSION NR: AP3004108

(equilibrium equations, symmetry conditions, and elasticity relationships) for determining displacements and stresses. Iterative processes are formulated for determining the states of stress which are, in the zero approximation, equivalent to the membrane-stress state, the pure flexural-stress state, and the states with large indexes of variation, as well as the iterative processes corresponding to the states of torsion and of plane strain at the edges. Through the combination of these iterative processes, the boundary conditions of the three-dimensional elasticity theory can be satisfied with an arbitrary degree of accuracy. The physical interpretation of the equations of the iterative processes is given. Certain conditions ensuring the asymptotic convergence of these iterative processes and thus determining the region of application of results obtained are briefly discussed. TITLE: Contribution to the construction of the two-dimensional equations of the theory of thin elastic plates

SOURCE: Prikladnaya matematika i mekhanika, v. 29, no. 1, 1965, 141-155

TOPIC TAGS: elasticity theory, elastic shell, applied mathematics, mechanical stress, strain measurement, stress calculation

ABSTRACT: The authors discuss ways to construct an approximate theory governing the calculation of thin elastic plates without employing assumptions typified by Kirchhoff's hypothesis. Up to now the only method of solving this problem was the method based on the use of power series or series expansions in Legendre polynomials. In some recent papers such problems have been handled by asymptotic integration of the equations of elasticity theory. In the present work the authors discuss the features of these methods and derive equations to which the asymptotic method reduces in the problem of the general strain of thin plates whose mean surface is related to an arbitrary orthogonal system of curvilinear coordinates. Orig. art. has: 59 formulas.

TITLE: On errors in the classical linear shell theory and on means of improving it

SOURCE: Prikladnaya matematika i mekhanika, v. 29, no. 4, 1965, 701-715

TOPIC TAGS: linear shell theory, improved classical shell theory, classical shell theory, asymptotic method, three dimensional elasticity equation

ABSTRACT: An asymptotic method of integrating the three-dimensional equations of the theory of elasticity is proposed for determining the stresses and displacements in closed shells in which the effect of support conditions is eliminated (for example, in a complete sphere). It is assumed that the curvatures of the middle surface of the shell change smoothly, that its reduced length is not too large, and that the stress distribution sought for can be formally constructed by means of the membrane theory under an arbitrary self-equilibrating

Card 1/3

L 64122-65

ACCESSION NR: AP5021303

system of stresses with components differentiable a sufficient number of times. The results obtained by this method are compared with data obtained by applying the classical (based on the Kirchhoff-Love hypotheses) theory of shells, and the effect of errors caused by assumptions made in its initial relationships on the final results is investigated. In order to compare both results, the final formulas obtained by the method proposed are expressed in terms of the classical shell theory. The error estimates given here take account of the index of variation t , and it is shown that these errors (which have in the classical theory an order of the nondimensional thickness h_*) can be essentially reduced (up to values of the order h_*^{2-2t}). The expressions for the elasticity relationships which must be used to achieve this improvement are derived. The comparison leads to the conclusion that a more exact classical shell theory can be proposed for the solution of the discussed problem in which the error (in the case when $t = 0$) will be of the order t^2 in comparison with unity. The effect of the variations in the state of stress on the values of errors in the classical theory is also discussed. Orig. art has: 42 formulas.

TITLE: Qualitative analysis of free vibration of elastic thin shells

SOURCE: Prikladnaya matematika i mekhanika, v. 30, no. 1, 1966, 94-108

TOPIC TAGS: shell, thin shell, shell vibration, shell natural frequency, vibration mode

ABSTRACT: An asymptotic method of integrating dynamic equations associated with free-vibration problems of the classic linear theory of elastic thin shells is presented. Equations of equilibrium, elasticity, and strain-displacement relationships, containing the frequency and displacement parameters, are taken from the author's "Theory of elastic thin shells" and are used as initial equations in investigating the free vibration of an elastic thin shell, by a method which is a "dynamic" version of the asymptotic method developed by the author in the above mentioned book for solving the static problem. The principal attention is paid to vibrations associated with a large index of variation in the states of stress and strain. The problem is solved in a rough approximation; the possibility of refinements is discussed. The asymptotic properties of expressions for determining the frequencies and the associated states of stress are analyzed in relation to the order of the magnitude of the nondimensional thickness of the shell, and to the density

Card 1/2

L 20606-66

ACC NR: AP6007581

and shape of nodal lines. The classification of free-vibration modes is established, simplified equations for determining them in the first approximation are derived, and qualitative analyses of their natural-frequency spectra are carried out. The characteristic features of the boundary conditions in problems not studied before are discussed only qualitatively. New concepts of "quasi-lateral" and "quasi-tangential" vibrations (characterized by the predominance of the lateral and tangential displacements, respectively) are introduced, as well as of the concepts their integrals, which are analogous to integrals with a large index of variation in the static problem where they describe the distributions of flexural and tangential stresses. Examples of examining the existence of certain modes of vibration, and the spectra of natural frequencies are given. Orig. art. has: 1 table and 38 formulas.

growth. The structure of soaps is affected by additions of NaCl or CaCl_2 .

TOPIC TERMS: soap oil dispersion structure, soap electrostatics, lithium stearate, lead stearate, aluminum stearate, eutectic mixture, lead stearate crystal, crystal, crystal aggregate, aluminum lithium stearate aggregate, finely dispersed particle

ABSTRACT: The authors studied the crystallization of lithium stearate soaps (and other stearates, widely used in the manufacture of lubricating greases and oil dispersions), and conducted electrodiffusion and x-ray studies of the crystalline soaps, their melts and the soap-oil dispersions prepared from them. The experimental specimens were prepared by special techniques developed by the authors. The results are photographic, x-rayed and spectroscopic. The crystalline soaps differed little in their crystal structure of stearate and other soaps, structures depending upon the soap cation, but differed in the details of the

Goniometric and X-ray analysis of crystals of 1,3,8-trinitronaphthalene. Zhur. Fiz.Khim. 25, 555-6 '51. (MLRA 4:5)
(CA 47 no.17:8457 '53)

1. L.Ya.Karpov Phys.-Chem. Inst., Moscow.

X-ray study of crystals of some nitro and halogen derivatives of benzene and naphthalene. G. A. Gol'der, G. S. Zhidnev, M. M. Umanski, and V. P. Glushkova (L. Ya. Karpov Phys.-Chem. Inst., Moscow). *Zhur. Fiz. Khim.* 26, 1250-65 (1962). The 1,8-dichloronaphthalene crystallizes from hexane in the form of elongated transparent plates, m. 87°, d = 1.51. Each plate has a 110° angle between the edges of rhombic prisms $c[001]$ and $m[100]$. The unit cell has $a = 11.6$, $b = 10.0$, $c = 7.9$ kX, d.(x-ray) = 1.53; the space group $C_{2h}^2 = P2_1/C$, 4 mols. per cell. It was detd. that $\{h0l\}$ is present only when $l = 2n$, and $\{0k0\}$ when $k = 2n$. Colorless crystals of 2,6-dichloro-1-nitrobenzene (from cyclohexane) have $a[100]$, $b[010]$, $c[001]$, $k[101]$. It crystallizes with 4 mols. in a monoclinic cell with $a = 5.82$, $b = 9.33$, $c = 14.2$ kX, $\beta = 91^\circ$, $d = 1.40$, d.(x-ray) = 1.51, its space group $C_{2h}^2 = P2_1/m$ or $C_{2h}^2 = P2_1$. Monoclinic crystals of 2,4,6-tribromo-1-nitrobenzene crystallize from chloroform. The unit cell has $a = 9.3$, $b = 12.4$, $c = 9.8$ kX, $\beta = 127^\circ 20'$, $d = 2.40$, d.(x-ray) = 2.54, and contains 4 formula units. It was estd. that $\{hkl\}$ is present only when $k + l = 2n$, $\{h0l\}$ when $k = 2n$ and $l = 2n$, and the $\{0k0\}$ is present only when $k = 2n$. The crystal has space group $C_{2h}^2 = A2/a$ or $C_{2h}^2 = Aa$. The benzophenone crystals from hexane have well-defined facets of rhombic prisms: $a[100]$, $b[010]$, $c[001]$, $m[110]$, $d[101]$, $k[201]$, and rhombic dipyramid $h[111]$. Its unit cell has $a = 8.0$, $b = 10.2$, $c = 12$ kX, d (by flotation method) = 1.1, d.(x-ray) = 1.05; 4 mols. per cell with space group $D_{2h}^2 = P2_12_12_1$. The $\{h00\}$ is present when $h = 2n$; $\{0k0\}$ when $k = 2n$; $\{00l\}$ only when $l = 2n$. Rhombic crystals of 1,3,5-trinitrobenzene have the following dimensions of a

unit cell: $a = 12.8$, $b = 27.0$, $c = 9.8$ Å, with 16 formula units in each. The space group $D_{2h}^2 = P_{nch}$. The golden-colored needles of 1,3,5,8-tetrinitronaphthalene (I) (from EtOH) gave complicated x-ray diffraction probably owing to "regular polysynthetic formation." X-ray study of these crystals at -110° eliminated the possibility of interferences due to thermal vibrations. Crystals obtained from other solvents (e.g. AmOAc, ligroin, AcOH) gave similar interferences in x-ray diagrams. Crystn. from the mixts. of acetone with benzene or with toluene led to formation of new compds., which were very unstable in the air. By choosing planes without diffuse spots these investigators were able to show that the unit cell of I has $a = 26.3$, $b = 7.75$, $c = 5.54$ kX, and when $d = 1.04$ there are 4 mols. in a cell. For such a cell the $\{h0l\}$ was estd. to be present only at $h = 2n$, $\{0kl\}$ when $k + l = 2n$. On these bases the space group can be assigned: $D_{2h}^2 = Pnam$ or $C_{2h}^2 = Pna2$. The x-ray study of 2,4,6-trinitrotoluene (II), with interferences analogous to I, is in disagreement with V. Hertel's expts. (C.A. 27, 5223). By choosing only well-defined diffraction patterns it was possible to det. that the unit cell of II has 4 mols. with $a = 20.2$, $b = 6.2$, $c = 7.7$ kX, and the space group $C_{2h}^2 = Pn/m$ or $C_{2h}^2 = Pn$. It is concluded that in II, as in I, no true monoclinic crystals are formed.

GOL'DER, G.A.

The crystal structure of trichlorobenzonitrile. ~~Gol'der, G. S., Zhurav, and M. M. Uman'skiy (Khim. Akad. Nauk SSSR, Moscow). Zhur. Fiz. Khim. 26, 1434-7 (1952); cf. C.A. 46, 6078. The mol. structure of 2,4,6-trichlorobenzonitrile was detd. by Fourier analysis. It is monoclinic; the space group is $C_{2h}^2/P2_1/c$. The unit cell has the dimensions $a = 4.10$, $b = 10.97$, $c = 10.81$ kX, and $\beta = 91^\circ 30'$; and contains 4 mols. The plane in which the mols. lie forms a 21° angle with the (100) plane of the crystal. The line through C_1 and C_6 in the ring forms a $34^\circ 30'$ angle with the (010) direction. The bond distances C_1-C (nitrile), C_1-C_2 , C_2-C_3 , C_3-C_4 , C_4-C_5 , C_5-C_6 , and $N-C$ (nitrile) are 1.47, 1.39, 1.41, 1.38, 1.70, 1.71, and 1.40 kX, resp. The C_1-C-C_2 angle is distorted about 2° .~~

X-ray determination of the structure of indigo and thionindigo. R. A. Gelfand, G. S. Zhurav, and G. A. Gleditsky. *Kristallografiya* 1, 13-20 (1958). The Bayer formula for indigo does not explain the absence of geometric isomers, the deep color, and the high chemical and physical stability of this mol. Many hypotheses were developed (Kuhn, C.A. 26, 6142; Hodgson, C.A. 40, 5045) to give an improved formulation. The authors obtained indigo and obtained good crystals. The elementary cell dimensions for indigo are: $a = 9.28$, $b = 5.74$, $c = 12.35$ Å; $\beta = 116^\circ 40'$. For thionindigo they are: $a = 7.82$, $b = 3.92$, $c = 20.3$ Å; $\beta = 101^\circ 40'$. In both compounds $Z = 2$; the space group is $P2_1/c$. The electron density projection on (010) for thionindigo and the stepwise approximation method delivered the following x, y, z coordinates: C₁: $x = 0.418$, $y = 0.098$; C₂: $x = 0.514$, $y = 0.081$; C₃: $x = 0.870$, $y = 0.125$; C₄: $x = 0.870$, $y = 0.188$; C₅: $x = 0.226$, $y = 0.214$; C₆: $x = 0.068$, $y = 0.177$; C₇: $x = 0.071$, $y = 0.118$; C₈: $x = 0.217$, $y = 0.091$; S: $x = 0.229$, $y = 0.008$; O: $x = 0.656$, $y = 0.108$ (C.A. numbering). The mol. includes with (010) an angle of 27° . In indigo the inclinations to all 8 planes of the elementary cell are considerable; the plane of the benzene ring is nearly parallel to (210). A 3-dimensional Fourier synthesis gave the following coordinates in indigo: for C₁: $x = 0.049$, $y = 0.907$, $z = 0.000$; C₂: $x = 0.103$, $y = 0.793$, $z = 0.142$; C₃: $x = 0.107$, $y = 0.885$, $z = 0.338$; C₄: $x = 0.277$, $y = 0.431$, $z = 0.212$; C₅: $x = 0.334$, $y = 0.365$, $z = 0.169$; C₆: $x = 0.373$, $y = 0.291$, $z = 0.087$; C₇: $x = 0.293$, $y = 0.402$, $z = 0.014$; C₈: $x = 0.208$, $y = 0.605$, $z = 0.029$; N: $x = 0.121$, $y = 0.791$, $z = 0.033$; O: $x = 0.059$, $y = 0.847$, $z = 0.219$. In indigo no simple bonds occur, also no classic double bonds. The bondings are intermediate between single and double valence bonds, and

(over)

only in the benzene rings but also in the heterocyclic portions of the molecule. A system of single π electron interaction is accomplished; an equimolecular linear-ionic constitution is not real. The distance N-O in the indigo unit is practically the sum of the ionic radii of both elements. No other bonds occur, but between the CO and N12 groups, the bonding is of the molal-hydrogen-bond type, and every unit is bound to 4 surrounding molal units by such H bonds. The thermal stability of indigo is thus explained. The electronic distribution shows a distinctly decreasing tendency from the center to the periphery of the molal unit, illustrating the thermal oscillations of the whole molal unit around its center of gravity. The absence of six-axis isomers is also explained by the results of the structure field. In the present paper, the

TITLE: An X-ray structural investigation of the oxygen vanadium
bronzes of sodium and potassium $\text{Me}_{0.5}\text{V}_2\text{O}_5$. (Rentgenograf-
icheskoye issledovaniye struktury kislorodnykh vanadiyevykh
bronzy natriya i kaliya $\text{Me}_{0.5}\text{V}_2\text{O}_5$.)

RELATIONSHIP: "Kristallografiya" (Crystallography), 1970, Vol. 6,
No. 2, pp. 217-225 (U.S.S.R.)

ABSTRACT: Experiment 1. The valency state of V in bronzes and in
vanadium-sulfur-oxygen catalysts is particularly of interest.
Crystals of composition $(\text{K}, \text{Na})_2\text{O} \cdot \text{V}_2\text{O}_4 \cdot 5\text{V}_2\text{O}_5$ were obtained as
black laths having a blue metallic lustre. They showed a
large number of faces including the simple forms 102, 101,
100, 001 variously developed. X-ray photo graphs assigned
them to the huc class $2/m = C_{2h}$. Weissenberg and oscill-
ation photographs (11.450 cm diameter camera) with Fe radia-
tion gave unit cell dimensions $a = 10.039$, $b = 3.605$, $c = 15.355$ Å
(all ± 0.005 Å) and $\beta = 109^\circ 12' \pm 3'$, for the sodium compound
 $\text{Na}_{0.5}\text{V}_2\text{O}_5$. This gives $V = 524.2$ Å³. The compound $\text{K}_{2.5}\text{V}_{12}\text{O}_{50}$
and $d_{001} = 9.57$ Å/cm² having $z = 1$ (0.97). d_{001} is then 3.60.

70-2-3/24

An X-ray diffraction investigation of the oxygen tungsten
bronze of sodium metavanadate $\text{Na}_2\text{O} \cdot \text{V}_2\text{O}_5$ (P. 1)

The possible space groups (from the extinction) were $A2/n$, $A/2$
and Am . On the basis of a knowledge of the crystal chemistry
of the end members V_2O_5 and of the W bronzes the group
 $A2/n$ was chosen. This is confirmed by the dimensions which
leads to the expectation of octahedral or trigonal bipyramids
(see J.P. Cooper - *Adv. Chem. Ser.*, 95, 1958). Main Mo radi-
ation 100 reflections were measured from a reticograph picture using
comparison scales. No extinction corrections were applied.
 $P(h, k)$ was constructed. A.D. Wadsley's determination of the
structure of $\text{Na}_2-x\text{V}_2\text{O}_5$ helped in solving this Patterson pro-
jection. Projections for both Na and V bronzes were constructed.
Several scans covering and this was the reason for repeating
Wadsley's work. The Patterson section at $y = 0$ was calculated
and the distances for the V bronze very close to those found
by Wadsley (Acta Crystallogr. 13, 833, 1958) for the Na
bronze. A table of interatomic distances is given. Similar
distances naturally occur in the $Mo-O$ distances (as observed
for V bronze first followed by Wadsley's value for the Na bronze);
 $Mo-O_1$ (2.20, 2.46); $Mo-O_2$ (2.49, 2.75); $Mo-O_3$ (2.50, 2.51);

Card 2/3

70-2-3/24

An X-ray diffractometric investigation of the crystal structure of vanadium dioxide V_2O_5 . (cont.)

$\text{V}-\text{O}_1$ (1.97, 1.91); $\text{V}-\text{O}_2$ (1.93, 2.22). The geometry of the structure is discussed. The structure is built from strongly distorted VO_6 octahedra. The distortion is so great that certain linkages are better regarded as trigonal bipyramids. The polyhedra differ greatly among themselves V-O distances within VO_6 of 1.97, 1.93, 1.91, 2.00 and 2.22 Å. There is a strong correlation with the structure of the V oxides. The alkali atoms lie in canals between the octahedra each surrounded by seven oxygens. Seven-fold coordination is rare but is also found in the ion $(\text{BiF}_6)^{-}$ and in Bi_2O_3 .

A Radiographic Structural Examination of
Naphthazarine

20-1186-23/13

in the elementary mesh conform the assumption (reference 1) that a center of symmetry exists in the molecule of the crystals of the 1st modification. The introduction of an inner hydrogen compound $O \dots H-O$ in the conjugated bond-system must have caused an essential change of the π -electronic interaction in the whole molecule. This must, in return, lead to a redistribution of the electronic density in the molecule. A complete radiographic analysis of the crystals of this modification was interesting therefore. The lengths of the bonds between the atoms in the molecule were computed (II) from the atomic coordinates computed from $p(0kl)$ (table 2). The computations of the distances between the atoms were carried out under the assumption that the molecule of the surface yz lies parallel. The angle formed by the bond-line $C_9 - C_{10}$ with the y -axis of the mesh, is 50° . The smallest distance between the carbon- and oxygen-atoms in various molecules is $3,10 \text{ \AA}$. The results of the radiographic structural analysis confirm the presence of a center of symmetry in the 1st modification of naphthazarine. As mentioned above, all 3 modifications precipitate simultaneously with the crystallization of the solution: 2 centrosymmetrical ones (A), and a none-centro-symmetrical one (B). The

Card 2/4

A Radiographic Structural Examination of Naphthazarine 20-118.2-23/43

recrystallization of each of these modifications leads in return to the formation of all these 3 modifications, though one of them prevails largely. It may thus be presumed that the transition of an isomer of an A-structure into an isomer of a B-structure (and vice-versa) takes place. This transition is explained with scheme III and was presumed in reference 4. The orientation in space of the molecule in the yz -surface achieved by the authors, is very similar to that for the centro-symmetrical modification 2) given in reference 3. A three-dimensional synthesis is required for determining the 3rd coordinate x and for defining precisely the obtained results. There are 1 figure, 2 tables, and 4 references, 1 of which is Slavic.

TITLE: The Radiographic Investigation of 1,4-di-Anilido-Anthraquinone and 1,4-Diresido-Anthraquinone (Radiograficheskoye issledovaniye 1,4-dianilidoantrakhinona i 1,4-diresidoantrakhinona)

PERIODICAL: Doklady Akademii Nauk SSSR, 1958, Vol. 119, Nr 1, pp. 87 - 89 (USSR)

ABSTRACT: Sulfo acids of 1,4-di-(arylamino)-anthraquinone form an important group of solid dyes for wool. The majority of the 1,4-di-(arylamino)-substitutes of anthraquinone are green. An exception is made by the derivatives in which all hydrogen atoms, in an ortho-position, of the aryl-residues are substituted. Such compounds as well as the corresponding alkyl-amino-and hydro-aryl-amino-derivatives have an intensive bright-blue color. In the presence of methyl-ethyl-groups or of bromine atoms in all ortho-positions of the phenyl residues or in the position of 2,3-anthraquinone respectively

Card 1/6

The Radiographic Investigation of 1,4-di-Arylamino-Anthraquinone and
1,4-Dimesido-Anthraquinone

cycles by hydrogen and is caused by the destruction of the conjugation system (Reference 1). It would be desirable to find a direct proof of the flat structure of the molecules of 1,4-di-(arylamino)-anthraquinone in the absence of spatial difficulties. For the purpose of deciding the problem of coplanarity of the benzene nuclei with the plane of the basic part of the molecule, crystals of both compounds mentioned in the title were radiographically measured. The results are given in table 1. From the dimensions of the elementary cell of the first compound can be assumed that the basic part of the molecule is more entirely or almost parallel with the ac-plane, as axis b is the shortest one (8,73 Å). From the conditions of symmetry of the spatial group

Card 3/6

11-11-1-23/52

The Radiographic Investigation of 1,4-Bis-Anilino-1,4'-Dicyanobenzene and
1,4-Dimesido-Anthraquinone

follows that a slip plane with a displacement along axis c runs vertical to axis b . Therefore the molecules occurring in the unit cell are oriented in layers which are perpendicular to axis b . A variant of this orientation is shown by figure 1. It admits a limitation of the benzene nucleus in relation to the other part of the molecule as well as a certain possible turn of the entire molecule in relation to the plane ac . Thus the packing of the molecules in the crystal does not require an additional change of the angle of rotation of the benzene nucleus as compared to the free molecule. The shortest axis in the crystal of the second compound is the a -axis (7,99 Å). Its length corresponds to the dimensions of the benzene nucleus as to the CH_3 -groups connected with it (9,8 Å). A solid packing of molecules in the crystal and the fulfilment of the conditions of symmetry of the spatial group for molecules of the second compound

Card 4/6

The Radiographic Investigation of 1,4-di-Amino-1-Anthraquinone and
1,4-Dione-1-Anthraquinone

of the methyl groups to all meta-positions of the benzene nucleus creates so great spatial difficulties that the coming out with the anthraquinone cycles from the planarity amounts to almost 90°. Thereby the inner-methyl linkage is considerably weakened. There are 11 references, 10 in the, and 5 references, all of which are Soviet.

Abstracts of the Effect of Temperature on the Metabolic Activity of Animals

1. The authors are V. S. Kiselev and P. P. Korneev. Institute of Mathematics and Mechanics, Siberian Branch of the USSR Academy of Sciences, Novosibirsk. 2. The work was carried out in the Laboratory of the Physics of the Plasma, Institute of Nuclear Energy, Academy of Sciences of the USSR, Moscow. 3. The authors are A. A. Gerasimov, A. A. Deryagin, and A. A. Kiselev. Institute of Nuclear Energy, Academy of Sciences of the USSR, Moscow. 4. The authors are V. V. Kiselev and V. V. Kiselev. Institute of Nuclear Energy, Academy of Sciences of the USSR, Moscow.

1. The first step is to identify the problem. This involves understanding the current situation and what needs to be changed.

TITLE:

The Crystal Structure and Density of Cerium Hydrides (Kristallicheskaya struktura i plotnost' gidridov tseriya)

PERIODICAL:

Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 7, pp 1488-1490 (USSR)

ABSTRACT:

Cerium hydrides with a composition of from $\text{CeH}_{0.2}$ to CeH_3 were investigated. The trihydride was produced in an apparatus described in an earlier paper (Ref 5). The samples poor in hydrogen were obtained by heating and by sucking off the liberated hydrogen. The composition of the hydrides was determined by measuring the hydrogen liberated in a solution of hydrochloric acid. The Debye powder patterns were recorded by means of the camera RKD. The values of the lattice periods are given by table 1. Up to the composition $\text{CeH}_{1.5}$ two cubical face-centered lattices exist, which correspond to the metal Ce and to the dihydride. The sample $\text{CeH}_{1.97}$ shows a phase in the period 5.55 Å. A further increase of the hydrogen content leads to a reduction of the period to 5.53 Å at $\text{CeH}_{2.73}$. If the com-

The Crystal Structure and Density of Cerium Hydrides

position CeH_3 is approached, the lines widen, so that exact calculation of the lattice period is rendered difficult. Because of the great sensitivity of cerium hydrides to vestiges of water, density was determined in an apparatus (Fig 1), in which argon was used as a pyknometric substance, and in which the volume of the sample was determined on the basis of a variation of pressure according to the Boyle-Mariotte law. The density of the various hydrides is given by table 2. It decreases up to the compound CeH_2 , after which it rises somewhat up to CeH_3 .

Figure 2 gives a graphical comparison of density variations with the X-ray pictures, the curve of which shows the presence of two phases (metallic cerium and CeH_2) up to the compound CeH_2 .

The lines of the metallic Ce then vanish. The phase with the periods $5.645 - 5.612 \text{ \AA}$, which was observed by M. C. Auphas-sorho (Refs 3,4) could not be found. There are 2 figures, 2 tables, and 8 references, 2 of which are Soviet.

TITLE:

The Use of X-Ray Phase Analysis in Chemical Technology (Priimeneniye rentgenovskogo analiza v khimicheskoy tekhnologii)

PERIODICAL:

Zvezdaye, Leningrad, 1974, Vol. 1, No. 1, 1-10 (USSR)

ABSTRACT:

The present paper lists the results of investigations carried out by the laboratories of the plant "Kryukovskiy" (Yaroslavl', GIKI-4, IRIIA, "Kryukovskiy", Leningrad, Fiziko-khicheskoy institut im. I. Ya. Khar'eva (Leningrad, Khimicheskoy Institut im. I. Ya. Khar'eva) and others. A standard domestic X-ray apparatus was used. Since the X-ray phase analysis has a low sensitivity for identifying it should not be used for determining the amount of impurities (less than 1-3%). The analysis of life and death is described: 1) a study of titanium dioxide and its impurities, the optimum production conditions of sulfate, 2) the study of solid oxide it was found by X-ray analysis that it is

yellow substance did not correspond to the usual red tetragonal modification of PbO , but to the yellow rhombic modification, and that the color was due to a polymorphous change. 3) By means of X-ray analysis it was possible to simplify the production control of active pyrolusite of the TAT. 4) Examinations of domestic and foreign reacting towers were carried out to determine the dispersion degree of the iron oxide. 5) Moreover, the production of thiourea was controlled with regard to dicyan-diamide. 6) The X-ray analysis was also successfully used in the examination of luminophores, and it also be applied for the examination of other substances (e.g. catalysts).

AUTHORS: Chamova, V.N. and Gol'der, G.A.
TITLE: X-ray investigation of the potassium carbonate
peroxyhydrate $K_2CO_3 \cdot 5H_2O_2$
PERIODICAL: Zhurnal strukturnoy khimii, v. 3, no. 2, 1962.
215 - 216

TEXT: One of the authors (Ref.2: Makarov, S.E., Chamova, V.N., Izv. Akad. Nauk SSSR, Otd. khim. nauk, v. 3, 1958, 1023) discovered a stable solid phase of the above composition. X-ray analysis of this substance was carried out by the powder and monocrystal method, and the crystal was found to belong to the orthorhombic system. The parameters of the elementary cell are : $a = 5.50$, $b = 6.64$, $c = 17.8$ A. The density of the peroxyhydrate was measured ($d = 2.02$). There are four molecules in the elementary cell, and the calculated density is $d = 2.01$.
